

The Student Who Knows Everything

Project Overview & Objectives — Team KUET_Titanium

1. Problem Statement

Every campus has one person who seems to know everything — which teacher wants assignments handwritten, which room the lab moved to, where to find last year's question papers, which office needs three signatures instead of two.

That person is usually a senior student. And every year, they graduate — taking years of hard-earned, practical knowledge with them. The next batch of students starts from zero, repeating the same confusion, asking the same questions, making the same mistakes their seniors already solved.

This knowledge is real, useful, and constantly needed — but it lives nowhere. It's scattered across group chats, word of mouth, and people's memory, with no system to capture it, no way to check if it's still true, and no way to pass it down reliably.

The added challenge: not all knowledge is equally trustworthy. A senior's advice from three years ago might be outdated. A tip from someone who's usually wrong isn't as valuable as one from someone who's consistently right. Any system built for this problem has to handle that difference — not just store information, but judge how reliable and current it is.

2. Our Solution

We're building an offline-first Android app that acts as a living, evolving memory for the campus community — a place where practical knowledge is captured once, verified by the community, and passed on to every new batch of students automatically, long after the person who knew it has graduated.

3. Objectives

- **Offline-First Android App**

The app works fully without an internet connection, since students often need answers in places with poor or no network — inside a lab building, near hostels, or on campus grounds with weak signal. Any updates sync automatically once a connection becomes available.

- **Flexible Knowledge Database**

Campus knowledge doesn't come in one shape — it can be a location, a contact, a warning, a document requirement, or a full process. Our database schema is built to hold all of these different knowledge types without forcing them into a rigid, one-size-fits-all format.

- **Searchable Knowledge Chunks**

Information is broken down into small, self-contained, tagged pieces rather than long unstructured posts. This makes search fast and precise — a query returns the exact answer needed, not a wall of text to dig through.

- **Guided Step-by-Step Roadmaps**

Some knowledge isn't a single fact but a process — getting a form signed, applying for a re-exam,

registering late for a course. For these, the app presents a clear, ordered roadmap (Step 1, Step 2, Step 3...) instead of a scattered explanation.

- **Data Validation & Lifespan**

Every piece of knowledge carries a freshness and validity status. Information ages — offices move, rules change, forms get replaced. The system flags outdated entries and allows the community to re-verify or correct them over time, so old information doesn't stay trusted forever.

- **Contribution Scores & Levels**

Not all contributors are equally reliable, and the app doesn't treat them as if they are. Users earn a score and a level based on the accuracy and usefulness of what they share, so the community naturally learns to trust proven contributors more — the same way everyone already trusts the senior who's always right, over the one who's usually right.

In short: we're not just building a knowledge-sharing app — we're building a trust-aware, self-updating memory for the campus, so that when the senior who knows everything graduates, everything they knew doesn't graduate with them.
